Gasoline direct injection (GDI), also known as petrol direct injection (PDI), is a mixture formation system for internal combustion engines that run on gasoline (petrol), where fuel is injected into the combustion chamber. This is distinct from manifold fuel injection systems, which inject fuel into the intake manifold. The use of GDI can help increase engine efficiency and specific power ...

Direct fuel injection is a very old idea Until the early 2000s, direct injection was mainly associated with diesel engines. However, gasoline direct injection isn't a new idea. The first engine to use direct injection was a V8 aircraft engine created by Leon Levasseur in 1902 – a hundred years before GDI became widely used in passenger cars.

How Direct Fuel Injection Works Gasoline engines work by sucking a mixture of gasoline and air into a cylinder, compressing it with a piston, and igniting it with a spark. The resulting explosion drives the piston downwards, producing power.

[Understand Direct Fuel Injection and How It Works](#)

Gasoline direct injection (GDI) is a fuel delivery system in gasoline internal combustion engines. The system represents the latest technologies in fuel injection and utilizes a high pressure common rail accumulator assembly which injects the fuel mixture directly into the engine's combustion chambers.

[What is Gasoline Direct Injection? \(with picture\)](#)

It's called direct injection, and it refers to how the fuel makes its way inside an engine's controlled-explosion room, better known as a combustion chamber. In a garden-variety gasoline engine with fuel injection, gasoline takes a more roundabout route than it does with the direct injection method.

Before we look inside the direct injection engine, let's view a quick second in the life of a standard gasoline engine (for a more complete look at the gasoline engine, check out How Car Engines Work). First, the fuel travels via pump from the fuel tank, through the fuel line and into fuel injectors that are mounted into the engine.

!What happens with the direct injection engine is you're squirting that liquid fuel into the cylinder, it gets on the cylinder walls and absorbs into the oil. What happens during the combustion event is the oil that is on the cylinder walls contains gasoline so it ignites and it burns off.

[Solving Gasoline Direct Injection Issues: The facts and ...](#)

Gasoline direct injection (GDI) can cause carbon buildup problems. It differs from traditional multiport fuel injection (MFI) in several ways. First, the tip of the fuel injector is located right in the combustion chamber, so the injector is subjected to very high compression and combustion pressures. That's different than an MFI injector that's located in the intake manifold and subject to only manifold vacuum.

Gasoline direct injection (GDI) is a more advanced version of multiport systems, where fuel is injected directly into the combustion chamber instead of the intake port. Direct injection improves combustion efficiency, increases fuel economy and lowers emissions.

[Direct Injection Engine vs. Port Fuel Injection](#)

Gasoline direct injection (GDI): – It is also known as petrol direct-injection engine and it is a fuel injection employed in latest four-stroke gasoline engines. In this technology, the gasoline gets highly-pressurized and than injected via a common rail fuel line directly into the combustion chamber of each cylinder.

Engines with gasoline direct injection produce the air-fuel mixture directly in the combustion chamber. Only fresh air flows into the intake port through the open intake valve. The fuel is injected directly into the combustion chamber by high-pressure injectors.
